General Tests and Assays

Physical Tests and Determinations

**Briefing**

616 Bulk Density and Tapped Density of Powders. The European Pharmacopoeia is the coordinating pharmacopeia for the international harmonization of the compendial standards for the Bulk and Tapped Density general chapter, as part of the process of international harmonization of monographs and general analytical methods of the European, Japanese, and United States pharmacopeias. The following section from the general chapter, which represents the ADOPTION STAGE 6 document, is based on comments from the United States Pharmacopeia and the Japanese Pharmacopoeia. The addition of a sentence on test conditions for Apparatus three has been accepted. The test conditions including the tapping height are specified in the expression of the results. Also, the note proposed at the end of last paragraph for compressibility index has been changed from USP local text to global text.

**Change to read:**

**TAPPED DENSITY**

The tapped density is an increased bulk density attained after mechanically tapping a container containing the powder sample. Tapped density is obtained by mechanically tapping a graduated measuring cylinder or vessel containing a powder sample. After observing the initial powder volume or weight, the measuring cylinder or vessel is mechanically tapped, and volume or weight readings are taken until little further volume or weight change is observed. The mechanical tapping is achieved by raising the cylinder or vessel and allowing it to drop under its own weight a specified distance by either of three methods as described below. Devices that rotate the cylinder or vessel during tapping may be preferred to minimize any possible separation of the mass during tapping down.

**Method I**

Apparatus—The apparatus (Figure 3) consists of the following:

- A 250-mL graduated cylinder (readable to 2 mL with a mass of 220 ± 44 g)
- A settling apparatus capable of producing, in 1 minute, either nominally 250 ± 15 taps from a height of 3 ± 0.2 mm, or nominally 300 ± 13 taps from a height of 14 ± 2 mm. The support for the graduated cylinder, with its holder, has a mass of 450 ± 10 g.
**Procedure**—Proceed as described above for the determination of the bulk volume ($V_0$). Secure the cylinder in the holder. Carry out 10, 500, and 1250 taps on the same powder sample and read the corresponding volumes $V_{10}$, $V_{500}$, and $V_{1250}$ to the nearest graduated unit. If the difference between $V_{500}$ and $V_{1250}$ is less than 2 mL, $V_{1250}$ is the tapped volume. If the difference between $V_{500}$ and $V_{1250}$ exceeds 2 mL, repeat in increments such as 1250 taps, until the difference between succeeding measurements is less than 2 mL. Fewer taps may be appropriate for some powders, when validated. Calculate the tapped density ($g/mL$) using the formula $m/V_F$ in which $V_F$ is the final tapped volume. Generally, replicate determinations are desirable for the determination of this property. Specify the drop height with the results. If it is not possible to use a 100-g test sample, use a reduced amount and a suitable 100-mL graduated cylinder (readable to 1 mL) weighing 130 $\pm$ 16 g and mounted on a holder weighing 240 $\pm$ 12 g. The modified test conditions are specified in the expression of the results.

**Method II**

**Apparatus and Procedure**—Proceed as directed under Method I except that the mechanical tester provides a fixed drop of 3 $\pm$ 0.2 mm at a nominal rate of 250 taps per minute.

**Method III**

**Apparatus and Procedure**—Proceed as directed in Method III—Measurement in a Vessel for measuring the bulk density. Repeat the procedure using 400 taps. If the difference between the two masses obtained after 200 and 400 taps exceeds 2%, carry out a test using 200 additional taps until the difference between succeeding measurements is less than 2%. Calculate the tapped density ($g/mL$) using the formula $M_f/100$ where $M_f$ is the mass of powder in the measuring vessel. Record the average of three determinations using three different powder samples.

The test conditions including tapping height are specified in the expression of the results.

Change to read:

**MEASURES OF POWDER COMPRESSIBILITY**

Because the interparticulate interactions influencing the bulk properties of a powder are also the interactions that interfere with powder flow, a comparison of the bulk and tapped densities can give a measure of the relative importance of these interactions in a given powder. Such a comparison is often used as an index of the ability of the powder to flow, for example the Compressibility Index or the Hausner Ratio as described below.

The Compressibility Index and Hausner Ratio are measures of the propensity of a powder to be compressed as described above. As such, they are measures of the powder’s ability to settle, and they permit an assessment of the relative importance of interparticulate interactions. In a free-flowing powder, such interactions are less significant, and the bulk and tapped densities...
will be closer in value. For poorer flowing materials, there are frequently greater interparticle interactions, and a greater difference between the bulk and tapped densities will be observed. These differences are reflected in the Compressibility Index and the Hausner Ratio.

**Compressibility Index**—Calculate by the formula:

\[ 100\left(\frac{V_0 - V_F}{V_0}\right) \]

- \( V_0 \) = unsettled apparent volume
- \( V_F \) = final tapped volume

**Hausner Ratio**—

\[ \frac{V_0}{V_F} \]

Depending on the material, the compressibility index can be determined using \( V_{10} \) instead of \( V_0 \). [15 (USP34)]

[NOTE—If \( V_{10} \) is used, it will be clearly stated in the results.]
